IMPACT FACTOR 6.1

DETERMINANTSOFCAPITALSTRUCTUREININDIA:A STUDY OF PHARMACEUTICAL AND CHEMICALINDUSTRIES

Dr.VEJANDLAVENKATARAMAKRISHNAMRAJU

AssociateProfessor WesleyPGCollegeSecunderabad,Telangana,India

Abstract

The present paper examines the factors influencing capital structure of the companies belonging to two industries namely Pharmaceuticals and Chemical that are listed at Mumbai Stock Exchause and Chemical that are listed at Mumbai Stock Exchnge Ltd. The secondary data has been used to achieve the objective of this study. The dataperiod ranges from 1999 to 2015 (i.e. 17 years). The chosen period covers a complete businesscycle i.e. both recessionary and booming phases of the industries. Here, the researcher has testedthe null hypothesis: that there is no significant relationship between the financial leverage andvarious independent variables. The statistics like coefficient of determination (R²), ANOVA (F), Durbin Watson, and regression coefficients resulting from the application of Multiple Regressionmodel were applied for the analysis of data. The results indicated that cost of debt and cost of equity are found having negative values of regression coefficients and the same are significant at 2% and 1% level respectively in case of pharmaceuticals.. The relationship between liquidity andleverage is negative (-0.199), but statistically significant. It means that the leverage of the firm is affected by liquidity of the firm. In case of steel industry two variables namely size of the firmand operating leverage are having positive and significant regression coefficients indicating apositive relationship with the leverage ratio whereas cost of debt, cost of equity, and DPR arefoundhaving negative and insignificant coefficients during theyears 2009 and 2015.

Keywords:Capitalstructure,Financialleverage,Debt/EquityRatio,Determinantsofcapitalstructure

Introduction

Capitalstructuredecisionsassumevitalsignificanceincorporatefinancialmanagementbecauseintoday 'sglobaleconomicenvironment,thesustainabilityofafirmheavilydependsonits

abilityandsuccessmanagingthisfunction. Traditionally corporate finance involves three important decisions. These are investment decisions, financing decisions and dividend decisions. Among these three decisions, the capital structure decisions are considered highly important asthey relate to long term financing of a firm. Capital structure refers to the different options usedby a firm in financing its assets. The capital structure of a company is a combination of debt, equity and other sources of finance that it uses to fund its long term assets. The choices betweendebt and equity to finance a firm's assets involve a trade-off between risk and return. The excessive use of debt may the survival of the whilea endanger firm, conservative of use debtmaydeprivethefirminleveragingreturntoequityowners. Thefirms' choiceofacombination of debt and equity depends on the various factors. In recent years many theories have been proposed to explain the determinants of capital structure of the firms. These theories suggest thatthe firmsselectcapital structuresdepending on the variouscosts and benefits associated with debt and equity financing.

ReviewofLiterature

Thereviewofliteraturein regardtodeterminantsofcapital structureisasgivenbelow:

Scott (1977) and Moore (1986) argue that along with ample non debt tax shield firms should alsohave considerable fixed assets, which they can use as mortgage to secure debt. It is also arguedthat unsecured loan is riskier than secured loan. So, one can envisage a positive relationshipbetween non-debt tax shield and leverage. Past empirical studies also show mixed results about the relationship of non-debt tax shield and leverage.

DeAngelo, Harry and Masulis, M S (1988) argued that even if bankruptcy, agency and relatedcosts are ignored, introduction of non-debt tax shields is enough for a firm to have an optimalcapital structure. And even if these costs are taken into account, an optimal capital structureexists, irrespective of availability of non-debt tax shields.

Smith and Watts, (1992) found that firms with high growth options and high cash flow volatilityhave incentives to reduce debt in their capital structure over the range of progressivityThis taxeffect suggests a negative association between growth opportunities and debt.

According

to signaling theory higher owth firms face greater information asymmetry and therefore are expected to have higher debt levels to signal higher quality. This signaling model predicts a positive association between growth opportunities and debt. According to a general to a positive association between growth opportunities and debt. According to a general to a positive association between growth opportunities and debt. According to a general to a positive association between growth opportunities and debt. According to a general to a positive association between growth opportunities and debt. According to a general to a gene

withmoregrowthopportunities are less likely to is suedebt for two reasons. First, the under investment problem suggests that firms generally is sue only risky debt that can be supported by assets-in-place.

Galai, D., and Masulis R. (2002) present the argument that stockholders of levered firms are prone to overinvest that gives rise to the classical conflict between shareholders and bondholders. But if the debt is secured against the fixed assets, the firm is restricted to use the borrowed funds for the same project for which it has borrowed. By this fact, creditors get an improved guarantee of repayment, and thus the chances of recovery are higher. Since this does not happen without collateralization of the fixed assets, the proportion of debt increases with the availability of more fixed assets in the balance sheet of the firm. Hence, the trade-off theory predicts a positive relationship between the tangibility and leverage in any firm. In contrast, the agency cost model predicts an egative relationship of tangibility with leverage in any firm

Grossman, S., and HartO. (2002) suggested that Tax and tax rate have important implications for business decisions and hence literature considers tax as one of the major determinants of capital structure. They use the absolute amount of the tax which the company pays in the particular financial year as a measure of tax.

Dimitrios L. Papadopoulos et al. (2007) investigate the present status and determinants of capitalstructure of firms listed in Athens Stock exchange. The analysis is based the data covering theperiod from 1995-2002. The study finds that determinants of capital structure is subjected tominor changes through years; differences between capital structure practices of retail firms andthatofindustrial firmsareminor; andprofitability'sthemaindeterminant capitalstructure.

Kapoor Sujata, Kanwal Anil (2008) attempt to identify the various factors that influence thecapital structure decisions of IT firms in India. The multiple regression analysis is used for theanalysisofpooleddataforsevenyearsi.e.2000to2006. The study suggests that debt equity ratio payout ratio is positively related to profits, cash flows and it has inverse relationship with the sales growth and market to book valueratio. Husam-Aldin Nizar Al-

Malkawai(2008)analysesthefactorsinfluencingcorporatecapitalstructuredecisionsofpubliclyquote dcompanies in Jordan. The analysis is based on 15-year unbalanced panel data covering the periodbetween1989and2003. The studyfinds that the factors affecting capital structure includes ize,

profitability, and age. The findings support for the agency costs hypothesis and are broadlyconsistentwith thepecking order hypothesis.

Titman, S., and Wessel R. (2009) argue in their paper about the negative relationship between size and probability of bankruptcy. Accordingly, trade-off theory predicts an inverse relationbetween size and bankruptcy and hence positive relationship between size and leverage. On theother hand if we take size as a proxy for information asymmetry then large firms tend to disclosemore information about their plans as they are closely watched by the capital market analysts. Sothe information asymmetry between the insiders and investors in the capital market is less forlarge firm. Accordingly, the pecking-order theory predicts a negative relationship between sizeandleverage.

Gupta Amitabh and Banga Charu (2010) bring out the determinants of corporate capital structureusingfactoranalysisandthemultipleregressions. Resultsoffactoranalysis indicate that leverage e, liquidity, profitability, growth and ownership structure are the major factors. According to the regression analysis on these factors shows leverage and liquidity to be the determinants of the capital structure for Indian companies. Majumdar, R (2010) tested the determinants of debtmaturity structure decisions and suggests that leverage is the important determinants of debtmaturity choice. He finds no evidence to conclude about the impact of effective tax rate on debtmaturity.

Abdul Rehman (2012) examines the factors affecting debt equity ratio of the companies listed atKarachi Stock Exchange (KSE) of Pakistan. One year of data i.e. 2009 is referred for the analysisbyusingregressionanalysis. The study found the positive relation of debt to to talassets, profitabil ity, current ratio with debt equity while cost of debt and capital intensity were found to be significant determinants of debt equity ratio in Pakistan.

Mehta Anupam (2012) investigates the determinants of capital structure for all firms in the areasof real estate, energy sector, construction sector, telecommunications sector, health care and industrial sectors for the period of 2005-2009. Two step analyses were done to analyze the effectof capital structure policy. At first stage correlation analysis and then backward multiple linearregression analysis was carried out at second stage. Profitability, Risk, Liquidity, Size and

Leverage of the firm are the determinants of capital structure policy. Size and the profitabilitywereconsidered as themost important determinants of capital structure policy.

Ebenezer Agyemang Badu (2013) examines the factors influencing capital structure of listedfinancial institutions in Ghana using fixed and random effects. Panel data (regression analysis)covering 2005-

2009 from these lected companies is used for the study. The results shows statistically significant and positive relationship between Age and liquidity but saw statistically insignificant relationship between profitability, collateral and dividend payout.

Boamah Kofi Baah, Richard Tawiah (2014) examines the determinants of capital structure andalso its effect on value of firm for companies listed on the Ghana Stock Exchange. The referenceperiod covers from 2006 to 2011. The ordinary least square (OLS) regression model is used in this study. The Price Volatility, Profit After-Tax, Earning per Share, Size, and Growth in Assets, Return on Equity, and Liquidity as explanatory variables and the Debt equity as the dependent variable uses these factors for the study. The study reveals that cost on equity, profit after tax and size of the company are the main determinants of capital structure of companies listed on the GSE. Profit After-

Taxhappenstobemostimportantvariablethatisconsideredbymostsectorsinpaying their dividend also.

Thus, the available literature on the subjectunder consideration provides a conclusion that empirical research work in this area has lagged behind the theoretical work, particularly indeveloping countries. Further, there is hardly any study on the influence of capital structure in Pharmaceutical and Chemical industries in India. Also the time period under reference of the above mentioned studies is relatively short. The present study is aimed to conduct a study which is free from the above mentioned limitations.

ScopeandResearchMethodologyoftheStudy

The scope of the study is limited to two industrial sectors of Indian economy which includes-Steel and Chemical. These sectors are chosen keeping into account the prominent role thesesectors play in the economy as India is the world's third-largest producer of crude steel (up fromeighth in 2003) and is expected to become the second-largest producer by 2016. The steel sectorin India contributes nearly two per cent of the country's Gross Domestic Product (GDP) andemploys over 600,000 people. The per capita consumption of total finished steel in the countryhasrisenfrom51Kgin2009-10toabout61.9Kgin2015-16.Similarly,theIndianchemical

industryplaysanimportantroleincountry's economic development. India's Chemical Industry is estimated at around 144 Billion USD at present. This sector forms a part of the basic goods industry and is a critical input for industrial and agricultural development. The chemical sector has witnessed growth of 13-14% in the last 5 years while petrochemicals have registered agrowth of 8-9% over the same period. The industry has a 14% weight in the overall Index of Industrial Production (IIP) and it accounts for about 2.11% of the nation's GDP.

The secondary data has been used to achieve the objective of this study. The data period rangesfrom 1999 to 2015 (i.e. 17 years) for the sample industries. The chosen period covers a completebusiness cycle i.e. both recessionary and booming phases of the industries. A sample of 120companies (60 units from each of the two industries) listed at BSE was selected using simplerandomsamplingtechniqueforthisstudy. The analysis regarding determinants of capital structur e has been carried out by dividing the above mentioned period into two sub-groups: (i)between 1999 and 2008(before sub-prime crisis of US); and (ii) between 2009 and 2015(aftersub-prime crisis). Here, the researcher has tested the null hypothesis: that there is no significant relationship between the financial leverage and various independent variables. 'Debt to equityratio' is taken as a measure of financial leverage i.e. a dependent variable. The independent variable taken for the regression analysis are-DPR(dividend payout ratio), COD(cost debt), SIZELOG10 (logofsize of firm), DSC (debts ervice capacity), LIQUIDITY (current ratio), COE (c ostofequity), NDTS (non-

debttaxshield),Operatingleverage),ProfitabilityandASSETTANG(assettangibility).

To begin with, step-wise correlation analysis was made so as to understand the problem of multi-co linearity in the data series. No problem of multi-co linearity was detected during the process.Afterthismultipleregressionanalysiswascarriedout.Thestatisticslikecoefficientofdetermina tion (R²), ANOVA (F), Durbin Watson, and regression coefficients resulting from theapplicationofMultipleRegression modelare presented in varioustables.

ResultsoftheStudy

Table-1 presents various statistics such as R, R², F-value and DW resulting from the regressionanalysis in case of Steel industry during the period 1999-2008. The value of R² is 0.176 whichmeans 17.6 percent of the variation in the debt-equity ratio is caused by the various factors in themodel. Durbin Watsontest which is applied to check the presence of autocorrelation obtains the

value 2.115. It means that data used does not show the problem of autocorrelation. This allows us to carry further analysis based on regression coefficients.

Table-1:ModelSummary&ANOVAincaseof SteelIndustry(1999-2008)

R	RSquare	Adjusted RSquare	Std. Error ofthe Estimate	Durbin- Watson	F	Sig
.461	.212	0.174	0.442	2.113	6.261	0.000

Table-2 shows the regression coefficients, t values and level of significance obtained byvarious independent variables for the pre crisis period (1999-2008). It is evident from the table that only two factors out of the eleven have significant value of regression coefficient. These factors are: asset tangibility and liquidity position. Asset tangibility exerts positive influence whereas liquidity exerts negative influence on the leverage. The regression coefficients of other factors are not significant and hence these factors do not put significant impacton leverage.

Let us now analyze the factors affecting leverage during 2009-2015. Table 3 exhibits the Modelsummary and ANOVA statistics resulting from the regression analyses in case of Steel industryduring the post-crisis phase. The value of R² is seen of moderate size 0.452. It means 45.2 percentvariation in the debt-equity ratio is caused by the model. It is obvious from the model that F-value is significant at 01 level of significance. It means explanatory variables play an importantrole in determining capital structure. Durbin Watson test obtains the value 1.893 which meansthatdatauseddoesnotshowtheproblemofautocorrelationasitisclosetotwo. This allows us to carry further analysis based on regression coefficients.

Table-4 shows the results of regression analysis run to identify the determinants of capitalstructure during the post crisis period(2009-2015) in case of Steel Industry. It is clear from thetable that the regression coefficient for the relationship between profitability of the firm andleverage is negative (-0.104). The hypothesis that profitability does not influence debtequityratioisacceptedbecausebetacoefficientisnotfoundsignificantat1%.Similarlytherelationship between growth of the firm and the leverage is positive and insignificant. However, size of the firm and operating leverage are having positive and significant regression coefficie ntsindicatingapositive relationship with the leverage ratio where a scost of debt, cost of **DPR** are found having negative and insignificant coefficients. The regressioncoefficientsconcerningliquidityfactorisfoundnegativeandsignificantat5%levelbecause P < 0.05.

Table-5 presents Model summary, F-Value andDW statistics resulting from the finallyselected regression model in case of Steel industry for the overall period (1999-2015). The value of R² is 0.290. It means 29 percent of the variation in the debt-equity ratio is explained by the model. The above is supported by ANOVA model which indicates that F-value is significant at 01 level of significance. It means the explanatory variables play an important role indetermining capital structure. Durbin Watson test value is 1.896 which means that da ta used do not show the problem of autocorrelation. The above analysis allows us to carryfurther analysis based on regression coefficients.

Table-6 shows the values of regression coefficients related to the Steel industry for the overallperiod of the study from 1999-2015. It is clear from the table that the values of regressioncoefficientsoffivevariablesnamelyassettangibility, size, liquidity, COD and operating lever age are significant at 5 percent level. While there is negative relationship of liquidity and COD with the other three variables namely asset tangibility, size of the firm and operating leverage have positive coefficients meaning thereby these have positive influence on debt-equityratio.

Table-7 shows the Model summary and ANOVA with reference to the Chemical industryduring the pre crisis phase from 1999-2008. It is clear from the table that the value of R² is0.409. It means 41 percent variation in the debt-equity ratio is caused by the model. The same is obvious from the F-value which is significant at 0.00 level. Durbin Watson test is alsoapplied to check the problem of autocorrelation. The test obtains the value 1.938 which is

indicatingthatthereisconclusiveevidenceregardingtheabsenceofautocorrelationandhencethe results are likely to bereliable.

Table-.9 presents the regression Model summary and ANOVA related to the Chemical industryduring the post crisis phase from 2009-2015. The value of R² is 0.425. It means 42.5 percentvariation in the debt-equity ratio is caused by the model. It is also obvious from the model that F-change is significant at 1 percent level. Durbin Watson test obtains a value 2.197 which is indicating the absence of autocorrelation. The aboveresults indicate that the model is reliable.

Table-9:ModelSummary&ANOVAincaseofChemicalIndustry2009-2015)

Model	R	R Square	Adjusted RSquare	Std. Error ofthe Estimate	Durbin-Watson	F	Sig.

Table-10 depicts the values of regression coefficients of independent variables during the phase-II (2009-2015). It is evident from this table that the regression coefficient related to operatingleverage and size are positive and significant at 5 percent level of significance. It implies highertheoperatingleverage, higherwill be the debt-equityratio. Similarly, larger the size, higheristhe D/E ratio. The variables growth, DSC, DPR and liquidity are having negative values of coefficient, but none of these are significant except liquidity. So these factors have no impact on the leverage of the firm except liquidity.

Table-5.11 shows the model summary and ANOVA(F) values for the overall period (1999-2015)in case of Chemical industry. The value of \mathbb{R}^2 is moderate (i.e 0.403). It means 40.3 percentvariation in the debt-

equityratioiscausedbythemodel.FurtherthecalculatedvalueofAnova(6.574) is significant at 1% level. It means that there is significant variance in capitalstructureratio.DurbinWatsonwasusedtochecktheproblemofautocorrelationwhichobtains 2.010valuesmeaningtherebythatthereisnoproblemofautocorrelationinvariousseries.

Table-11:ModelSummary&ANOVAincaseofChemicalIndustry(1999-2015)

			Adjusted R	Std.Errorof			
Model	R	RSquare	Square	theEstimate	Durbin-Watson	F	Sig.

Ī	1	0.635	0.403	0.395	1 1 547	2.010	6.574	.000
	1	0.033	0.403	0.373	1.572	2.010	0.574	.000

Table-12 shows the regression coefficients resulting from the finally selected capital structuremodel for the overall period (i.e1999-2015) in case of Chemical Industry. It may be seen in thetablethattherelationshipbetweenprofitabilityofthefirmandleverageispositivebutinsignificant. The table also indicates that the relationship between growth of the firm and theleverage is negative but insignificant. Further COD, COE are found having negative values ofregressioncoefficients and the same are significant at 2% and 1% level respectively. The relationship between liquidity and leverage is negative (-0.199), but statistically significant. Itmeans that the leverage of the firm is affected by liquidity of the firm. The regression coefficient of debt service capacity and operating leverage is negative and significant. The former indicatesthe negative relation with the leverage and the latter indicates a positive relation. It means that increase in the values of DSC, decreases the value of leverage. So the hypothesis of no impact of DSC ondebtequityratioisrejected. Operating leverage has turned out to be significant determinant of leverage .Further, NDTS has turned as significantly related with the leverage. So,the results yielded by multivariate regression brought model. have clearly that the independent variables under the model exert moderate level of influence on debtequityratio.NDTS,operatingleverage,costofdebtandcostofequity,DSC,liquidityhaveturnedtobethes ignificant factors in case of Chemical industry, at the overall level.

After the Chemical industry we investigated the factors affecting debt-equity ratio in case of Computer industry. Table-5.13 exhibits the Model summary and ANOVA results in case of this industry for the pre-crisis phase (1999-2008). The value of R² is found small (i.e0.238). This indicates that 23.81 percent variation in the debt-equity ratio is explained by the model. It is also supported by F-value which is significant at .01 level of significance. It means explanatory variables play an important role in determining capital structure. Durbin Watson test which is applied to check the problem of auto correlation. This test obtains a value 2.148 which means that data used do not show the problem of autocorrelation. This allows us to carry further analyses based on regression coefficients.

Conclusion

The analysis of data, about the influence of various independent factors on leverage, has broughtout some interesting findings. The values of R square work out between 0.21 and 0.45 which refers that the influence of various explanatory factors under reference is from lower to moderate capital structure. In chemical industry the variables cost of debt, cost of equity, liquidity and service capacity are having negative regression coefficients during 1999-2008 which are significant at 5 percent level of significance. During 2009-2015, the variables growth, DSC, DPR and liquidity are having negative values of coefficient, but none of these are significant

exceptliquidity. Attheoveralllevel, cost of debtand cost of equity are found having negative values of

regressioncoefficients and the same are significant at 2% and 1% level respectively. The relationship between liquidity and leverage is negative (-0.199), but statistically significant. Itmeans that the leverage of the firm is affected by liquidity of the firm. In case of steel industrytwo variables namely size of the firm and operating leverage are having positive and significant regression coefficients indicating a positive relationship with the leverage ratio whereas cost ofdebt, cost of equity, and DPR are found having negative and insignificant coefficients during theyears 2009 and 2015. The values of regression coefficients of five variables namely assettangibility, size, liquidity, COD and operating leverage are significant at 5 percent level in this industry during 1999-2015. While there is negative relationship of liquidity and COD with theother three variables namely asset tangibility, size of the firm andoperating leverage havepositive coefficients meaning therebythesehavepositive influenceon debt-equity ratio. Thus, the aboveresults need to bekept in mindwhile deciding the capital structure of a firm.
